(54) IMPROVED PROCESS FOR CATALYTICALLY DEWAXING GAS OIL

(71) We, MOBIL OIL CORPORATION, a Corporation organised under the laws of the State of New York, United States of America, of 150 East 42nd Street, New York, New York, 10017, United States of America, do hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:-

This invention relates to a process for dewaxing petroleum oils and fractions thereof by selectively removing normal paraffinic and other undesirable hydrocarbons from petroleum oils in which they are present in admixture with other hydrocarbons, in order to lower the pour point of such oils. More particularly, the invention relates to an improved single-step process for selectivity removing normal paraffinic and other undesirable hydrocarbons from petroleum oils by contacting same with a specific zeolite catalyst in the presence of a large amount of co-fed water.

It is well known in the art to form various lubricating oils from hydrocarbon fractions derived from petroleum crudes. A heretofore practiced common procedure known in the art is to extract these hydrocarbon fractions with various solvents so as to give a raffinate of a desired high viscosity index, such material being resistant to changes in viscosity with changes in temperature and thus being useful under varying operating conditions. Moreover, it is particularly desired that the lube oil have a low pour point so that it can be effectively used at low temperature conditions, since excessive thickening at low temperature is often unacceptable. It is also known in the art to carry out dewaxing operations by contacting hydrocarbon fractions with crystalline aluminosilicate zeolites having pore sizes of about 5 Angstrom units so as to selectively remove normal paraffins.

The present invention is concerned with an improved process for dewaxing normal paraffin-containing oils which is more economical than conventional solvent dewaxing procedures or catalytic dewaxing procedures involving 5 Angstrom unit zeolites and which, with certain feedstocks, produces a higher product yield with equivalent or higher pour point reduction and prolonged catalyst cycle time between regenerations.

Trace amounts of water used to promote various catalytic reactions, not including gas oil dewaxing, is known in the art. For example, U.S. Patent 3,546,100 teaches restricting the partial pressure of water in contact with a hydrocracking catalyst during hydrocracking of a hydrocarbon compound to within the range of 10 to 130 mm. U.S. Patent 3,649,524 teaches a high temperature reforming process using only 8-20 ppm water.

high temperature reforming process using only 8-20 ppm water.

Somewhat larger amounts of water have been used in high temperature catalytic dehydrogenation of hydrocarbons (U.S. Patent 3,907,921), wherein 25-3000 ppm of water is used; and in hydrodesulfurization of gas oils and cycle oils (U.S. Patent 3,720,602) wherein 5 to 50 percent of water is injected. In the latter patent, the catalyst material used does not include zeolite materials.

The use of large amounts of water, i.e. about 0.1 to about 15 moles water/mole

The use of large amounts of water, i.e. about 0.1 to about 15 moles water/mole hydrocarbon feedstock, would be expected, based upon the teaching of the art, to destroy conventional porous, siliceous heterogeneous catalysts, such as used in the present method.

U.S. Patent 3,755,138 discloses a two-step process for dewaxing hydrocarbon oil feedstocks boiling above about 650°F having an intermediate pour point. One step of the patent process comprises solvent dewaxing and the other step comprises contact with a ZSM-5 type of zeolite in the absence of co-fed water. U.S. Patent Re. 28,398 discloses dewaxing a hydrocarbon oil boiling above 350°F by shape selective cracking and

	nydrocracking over a zeolite of ZSM-5 type without co-fed water.	
	This invention relates to improved processing of gas oils wherein said processing comprises	
	contacting a gas oil feedstock in the presence of from about 0.1 to about 15 moles of co-fed water/mole of gas oil feedstock with a catalyst comprising a crystalline aluminosilicate zeolite	
5	characterized by a silica/alumina mole ratio of at least 12 and a constraint index, hereinafter	5
-	defined, within the approximate range of 1 to 12.	J
٠	The feedstock intended for treatment in accordance with the present invention may be	
	generally defined as hydrocarbon oils boiling above about 350°F and particularly between	,
	about 350°F and about 1,100°F. Processing of such feedstocks having a high nitrogen content	•
10	of from about 0.01 to about 3 wt. percent is most advantageously benefited by the present	10
	improved processing technique.	
	The crystalline aluminosilicate zeolites used in the catalyst composition of the process of	
	this invention are referred to generally as ZSM-5 type or as behaving like ZSM-5 and include	
15	ZSM-5, ZSM-11, ZSM-12, ZSM-35 and ZSM-38, more particularly described hereinafter.	
13	The catalyst composition useful in this invention comprises a crystalline aluminosilicate zeolite characterized by a silica/alumina mole ratio of at least 12 and a constraint index of	15
	from about 1 to about 12, non-limiting examples of which include ZSM-5, ZSM-11, ZSM-12,	
	ZSM-35 and ZSM-38.	
	Zeolite ZSM-5 is taught by U.S. Patent 3,702,886. In a preferred synthesized form, the	•
20	zeolite ZSM-5 for use in the catalyst composition useful in this invention has a formula, in	20
	terms of mole ratios of oxides in anhydrous state, as follows:	
	$(0.9 \pm 0.2) \text{ M}_2\text{O} : \text{Al}_2\text{O}_3 : \text{xSiO}_2$	
	$\overline{\mathbf{n}}$	
25	wherein M is selected from a mixture of alkali metal cations, especially sodium, and	<u></u>
25 .	tetraalkylammonium cations, the alkyl groups of which preferably contain 2 to 5 carbon	25
	atoms, and x is at least 5. Particularly preferred is a zeolite having the formula in the anydrous state as follows:	
	$(0.9 \pm 0.2) \text{ M}_2\text{O}: \text{Al}_2\text{O}_3: \text{ZSiO}_2$	•
	(0.5 = 0.2) M ₂ O : Al ₂ O ₃ : 25lO ₂	
30	wherein Z is from greater than 30 to about 350 or higher.	30
	Zeolite ZSM-11 is taught by U.S. Patent 3,709,979. In the as synthesized form, the zeolite	
	ZSM-11 for use in the catalyst composition useful in this invention has a formula, in terms of	
	mole ratios of oxides in the anhydrous state, as follows:	
25	$(0.9 \pm 0.3) M_{20} : Al_{2}O_{3} : 20 \text{ to } 90 \text{ SiO}_{2}$	
35	uberein Mic a mixture of at least one of the queternor estimate of a Court V. A. January C.	35
	wherein M is a mixture of at least one of the quaternary cations of a Group V-A element of the Periodic Table and alkali metal cations, especially sodium. The original cations can be	
	present to that the amount of quaternary metal cations is between 10 and 90 percent of the	•
	total amount of the original cations. Thus, the zeolite can be expressed by the following	
40	formula in terms of mole ratios of oxides:	40 ·
	$(0.9 \pm 0.3) (xXR_4 + 1-xM_2O) : Al_2O_3 : 20 \text{ to } 90 \text{ SiO}_2$	
	<u> </u>	
	wherein R is an alkyl or aryl group having between 1 and 7 carbon atoms, M is an alkali metal	·
15	cation, X is a group V-A element, especially a metal, and x is between 0.1 and 0.9.	4-
45	Zeolite ZSM-12 is taught by U.S. Patent 3,832,449. ZSM-35 is described in U.S. Patent No. 4,016,245. This zeolite can be identified, in terms	45
	of mole ratios of oxides and in the anhydrous state, as follows:	
	$(0.3 - 2.5)R_2O: (0 - 0.8)M_2O: Al_2O_3: xSiO_2$	•
	wherein R is an organic nitrogen-containing cation derived from ethylenediamine or	
50	pyrrolidine, M is an alkali metal cation and x is greater than 8, and is characterized by a	50
	specified X-ray powder diffraction pattern.	•
	In a preferred synthesized form, zeolite ZSM-35 has a formula, in terms of mole ratios of	
	oxides and in the anhydrous state, as follows:	
55	(0.4 - 2.5)R ₂ O: (0 - 0.6)M ₂ O: Al ₂ O ₃ : ySiO ₂ wherein R is an organic nitrogen-containing cation derived from ethylenediamine or	
55	pyrrolidine, M is an alkali metal, especially sodium, and y is from greater than 8 to about 50.	5 5
	ZSM-38 is described in U.S. Patent No. 4,046,859. This zeolite can be identified, in terms	
	of mole ratios of oxides and in the anhydrous state, as follows:	
	$(0.3 - 2.5)R_2O : (0 - 0.8)M_2O : Al_2O_3 : xSiO_2$	٠.
60	wherein R is an organic nitrogen-containing cation derived from a 2-(hydroxyalkyl)	60
	trialkylammonium compound, x is greater than 8 and M is an alkali metal cation, and is	
	characterized by a specified X-ray powder diffraction pattern.	
	In a preferred synthesized form, the zeolite has a formula, in terms of mole ratios of oxides	
65	and in the anhydrous state, as follows: $(0.4 - 2.5)R_2O : (0 - 0.6)M_2O : Al_2O_3 : ySiO_2$	65 -
0,5	(0.1 20)1120 . (0 . 0.0)1120 . 11203 . 30102	03 .

20

25

40

wherein R is an organic nitrogen-containing cation derived from a 2-(hydroxyalkyl) trialkylammonium compound, wherein alkyl is methyl, ethyl or a combination thereof, M is an alkali metal, especially sodium, and y is from greater than 8 to about 50.

Although the zeolites herein described have unusually low alumina contents, i.e. high silica to alumina ratios, they are very active even when the silica to alumina ratio exceeds 30. The

to alumina ratios, they are very active even when the silica to alumina ratio exceeds 30. The activity is surprising since catalytic activity is generally attributed to framework aluminium atoms and cations associated with these aluminum atoms. These catalysts retain their crystallinity for long periods in spite of the presence of steam at high temperature which induces irreversible collapse of the framework of other zeolites, e.g. of the X and A type. Furthermore, carbonaceous deposits, when formed, may be remoed by burning at higher than usual temperatures to restore activity. In many environments the zeolites of this class exhibit very low coke forming capability, conducive to very long times on stream between

burning regenerations.

An important characteristic of the crystal structure of the zeolites for use herein is that they provide constrained access to, and egress from, the intracrystalline free space by virtue of

15

35

provide constrained access to, and egless from the intractystamme and pore windows of about a size such as would be provided by 10-membered rings of oxygen atoms. It is to be understood, of course, that these rings are those formed by the regular disposition of the tetrahedra making up the anionic framework of the crystalline aluminosilicate, the oxygen atoms themselves being bonded to the silicon or aluminum atoms at the centers of the tetrahedra. Briefly, the preferred type catalysts useful in this invention possess, in combination: a silica to alumina ratio of at least about 12; and a structure providing constrained access to the crystalline free

The silica to alumina ratio referred to may be determined by conventional analysis. This ratio is meant to represent, as closely as possible, the ratio in the rigid anionic framework of the zeolite crystal and to exclude aluminum in the binder or in cationic or other form within the channels. Although catalysts with the silica to alumina ratio of at least 12 are useful, it is preferred to use catalysts having higher ratios of at least about 30. Such catalysts, after

activation, acquire an intracrystalline sorption capacity for normal hexane which is greater than that for water, i.e. they exhibit "hydrophobic" properties. It is believed that this hydrophobic character is advantageous in the present invention.

The type zeolites useful in this invention freely sorb normal hexane and have a pore dimension greater than about 5 Angstroms, or, if elliptical in pore shape, at least the size of the pores in ZSM-5. In addition, the structure must provide constrained access to larger molecules. It is sometimes possible to judge from a known crystal structure whether such constrained access exists. For example, if the only pore windows in a crystal are formed by 8-membered rings of oxygen atoms, then access to molecules of larger cross-section then normal hexane is excluded and the zeolite is not of the desired type. Windows of 10-membered rings are preferred, although, in some instances, excessive puckering or pore blockage may render these catalysts ineffective. Twelve-membered rings do not generally appear to offer sufficient constraint to produce the advantageous conversions. Also, structures can be conceived due to pore blockage or other cause, that may be operative:

Rather than attempt to judge from crystal structure whether or not a catalyst possesses the necessary constrained access, a simple determination of the "constraint index" may be made by passing cotinuously a mixture of an equal weight of normal hexane and 3-methylpentane over a small sample, approximately 1 gram or less, of catalyst at atmospheric pressure according to the following procedure. A sample of the catalyst, in the form of pellets or extrudate, is crushed to a particle size about that of coarse sand and mounted in a glass tube. Prior to testing, the catalyst is treated with a strem of air at 1000°F for at least 15 minutes. The catalyst is then flushed with helium and the temperature adjusted between 550°F to give an overall conversion between 10% and 60%. The mixture of hydrocarbons is passed at 1 liquid hourly space velocity (i.e., 1 volume of liquid hydrocarbon per volume of catalyst per hour) over the catalyst with a helium dilution to give a helium to total hydrocarbon mole ratio of 4:1. After 20 minutes on stream, a sample of the effluent is taken and analyzed, most

4:1. After 20 minutes on stream, a sample of the effluent is taken and analyzed, most conveniently by gas chromatography, to determin the fraction remaining unchanged for each of the two hydrocarbons.

The "constraint index" is calculated as follows:

Constraint Index = log10 (fraction of n-hexane remaining)
log 10 (fraction of 3-methylpentane remaining)

The constraint index approimates the ratio of the cracking rate constants for the two hydrocarbons. Catalysts suitable for the present invention are those having a constraint index in the approximate range of 1 to 12. Constraint Index (CI) values for some typical catalysts, including those useful herein, are:

40	These values were determined by standard technique. The radiation was the K-alpha doublet of copper, and a scintillation counter spectrometer with a strip chart pen recorder was used. The peak heights, I, and the positions as a function of 2 times theta, where theta is the Bragg angle, were read from the spectrometer chart. From these, the relative intensities, 100	40
45	I/Io, where Io is the intensity of the strongest line or peak, and k (obs.), the interplanar spacing in Angstrom units, corresponding to the recorded lines, were calculated. It should be understood that these X-ray diffraction patterns are characteristic of all the species of the above respectively identified zeolites. Ion exchange of the sodium ion with cations reveals substantially the same pattern with some minor shifts in interplanar spacing and variation in	45
50	relative intensity. Other minor variations can occur depending on the silicon to aluminum ratio of the particular sample, as well as if it has been subjected to thermal treatment. Zeolites ZSM-5, ZSM-11 and ZSM-12 for use in the process of this invention are prepared as indicated in their respective patents, as referred to above.	50
55	Zeolite ZSM-35 can be suitably prepared by preparing a solution containing sources of an alkali metal oxide, preferably sodium oxide, an organic nitrogen-containing oxide, an oxide of aluminum, an oxide of silicon and water and having a composition, in terms of mole ratios of oxides, falling within the following ranges:	55

TABLE 2 Broad Preferred 5 R ⁺ R ⁺ + M ⁺ 0.02 - 1.0 0.3 - 0.9 10 0H/SiO ₂ 0.05 - 0.5 0.07 - 0.49 10 H ₂ O/OH ⁻ 41 - 500 100 - 250 SiO ₂ /Al ₂ O ₃ 8.8 - 200 12 - 60 15 wherein R is an organic nitrogen-containing cation derived from pyrrolidine or ethylenediamine and Mis an alkali metal ion, and maintaining the mixture until crystals of the zeolite are formed. (The quantity of OH ⁻ is calculated only from the inorganic sources of alkali without any organic base contribution). Therefare, the crystals are separated from the liquid and recovered. Typical reaction conditions consist of heating the foregoing reaction mixture to a temperature of from about 90°F to about 40°F for a period of time of from about 60°W with the amount of time at a temperature in such range being from about 6 hours so about 10°W with the amount of time at a temperature in such range being from about 6 hours so about 40°W with the amount of time at a temperature in such range being from about 6 hours separated from the reaction medium, as by cooling the whole to room temperature, filtering and water washing. The crystalline product is diried, e.g. at 230°F, for from about 8 to 24 hours. Zeolite ZSM-38 can be suitably prepared by preparing a solution containing sources of an alkali metal oxide, preferably sodium oxide, an organic nitrogen-containing oxide, an oxide of aluminum, an oxide of silicon and water and having a composition, in terms of mole rating of oxides, falling within the following ranges: 35 TABLE 3 Broad Preferred 40 R ⁺ R ⁺ N ⁺ 0.2 - 1.0 0.3 - 0.9 45 OH/SiO ₂ 0.05 - 0.5 0.07 - 0.49 H ₂ O/OH ⁻ 41 - 500 100 - 250 SiO ₂ /Al ₂ O ₃ 8.8 - 200 12 - 60 50 wherein R is an organic nitrogen-containing cation derived from a 2-(hydroxyalkyl) trialkylammonium compound and M is an alkali metal ion, and maintaining the mixture until crystals for the zeolite are formed. combination with a support or binder material such as, for example, a porous inorganic oxide support or a clay binder. Non-limiting examples of such binder materials include alumina, zirconia, silica, magnesia, thoria, titania, boria and combinations thereof, generally in the form of dried inorganic oxide gels and gelatinous precipitates. Suitable clay materials include, by way of example bentonite and kieselguhr. The relative proportion of suitable crystalling aluminosilicate zeolite of the total composition of catalyst and binder or support may vary widely with the zeolite content ranging from between about 30 to about 90 percent by weight and more usually in the range of about 50 to 80 percent by weight of the composition. Operating conditions employed in the process of the present invention are critical. Such conditions as temperature, pressure, space velocity, molar ratio of co-fed water to gas oil 10 feedstock, absence or presence of added hydrogen, and the presence of any diluents will have important effects on the process. The process of this invention is conducted in the liquid or mixed gas-liquid phase and with or without added hydrogen by contact in a reaction zone, such as, for example, a fixed bed of catalyst composition, under conversion effective conditions, said catalyst composition, under conversion effective conditions, said catalyst composition being characterised, as synthesized, as comprising one or more of the above-defined zeolite compositions. This process may be conducted in either batch or fluid bed operation with attendent benefits of either operation readily obtainable. The present improved process may be carried out at a temperature of between about 450°F and about 800°F, preferably from about 500°F to about 750°F, and at pressures ranging from about 50 psig up about 3000 psig, preferably from about 100 psig to about 1000 psig. The liquid hourly space velocity (LHSV) may be maintained at from about 0.1 hr⁻¹ to about 2 hr-1. Hydrogen circulation may be maintained at from 0 to about 10,000 scf/bbl. The preferred amount of co-fed water is from about 0.1 to about 5 moles of water/mole of gas oil feedstock. Within these limits the conditions of temperature and pressure will vary considerably depending upon equilibrium considerations and exact feed material. Optimum conditions are those in which maximum yields of desired dewaxed products are obtained and hence temperature and pressure will vary within a range of conversion levels designed to provide the highest selectivity and maximum yield. The starting feed materials for the present improved process are petroleum stocks boiling above about 350°F and containing straight chain and slightly branched chain hydrocarbons which selectively converted utilizing a catalyst composition as hereinabove particularly The improvement realized by way of the present process is substantial in that coking and aging rates of the catalyst are controlled while conversions remain favorable. The zeolite catalysts above defined for use herein are found to be hydrophobic and unique in their ability to uitlize the large molar equivalents of co-fed water to resist coking and aging at the activity levels maintained in the present process. The following specific examples will serve to illustrate the process of the present invention, without unduly limiting same. Examples 1 and 8 illustrate the preparation of suitable catalysts. Examples 2. 4 and 7 are incuded for comparison. Example 1 A silicate solution containing 90.9 pounds Q-Brand sodium silicate (8.8 wt. %Na₂O, 28.5 45 wt. % SiO, and 62.7 wt. % H2O). 52.6 pounds H2O, and 118 grams Daxad 27 dispersant (sodium salt of polymerized substituted benzoid alkylsulfonic acid combined with an inert inorganic suspending agent) was mixed in a mixing nozzle with an acid solution containing 1430 grams Al₂(SO₄)₃. 14 H₂O. 3440 grams H₂SO₄. 4890 grams NaCl. and 54 pounds H₂O to form a gel which was discharged into a 30 gallon autoclave to which 1180 grams of H2O has 50 been previously added. The gel was whipped by agitation and 2840 grams of NaCl was added and thoroughly blended. The agitation was stopped and an organic solution containing 2780 grams tri-n-propylamine. 2390 grams n-propyl bromide, and methyl ethyl ketone was added as a layer on top of the gel. The autoclave was sealed and heated to about 220°F without agitation and held there for 14-15 hours to prereact the organics. At the end of the prereaction period the agitation was commenced at 90 rpm to start the initial crystallization period. After about 75-80 hours, the temperature was raised to 320°F and held there for about 3 hours to complete crystallization. The excess or unreacted organics were flashed off and the contents of the autoclave were cooled and discharged. Chemical analysis of the washed crystalline product was 2.21 wt. % Al₂O₃. 94.9 wt. % SiO₂. 0.81 wt. % Na. 0.67 wt. % N. and 8.2 wt. % carbon, and it was identified by X-ray as ZSM-5. After drying at about 250°F, the zeolite was mixed with alpha-alumina monohydrate and

H₂O (65% zeolite. 35% alumina binder on ignited basis). then extruded to form 1/16 inch pellets. The pellets were calcined in nitrogen atmosphere for 3 hours at 1000°F, ion exchanged with 1 normal NH₄Cl at room temperature for 1 hour using 5 milliliters solution

10

per gram of dry zeolite, water-washed, and finally calcined in 100% air for 3 hours at 1000°F. Examples 2-7

The catalyst material prepared in Example 1, sized to 30-60 mesh, was charged to a 5/16th -inch I.D. stainless steel tubing reactor with provision for water injection at the reactor inlet 5 from a positive displacement pump. Six separate runs were conducted in this reactor, each with 5 or 10 cc of fresh catalyst, under varying conditions and for different times on stream. The feedstock to the reactor was a 650-760°F Arab Gas Oil having a pour point of 55°F and a specific gravity of 0.8866. No hydrogen was added to the reactor for these runs. Reaction conditions and results are reported hereinafter in Table 4.

From the information generated by Examples 2-7, it is observed that aging rates were high at the reaction pressures used when water was not co-fed to the reactor, The beneficial affect of the large amounts of co-fed water on coke lay-down is clear by comparison of the examples

run with and without water injection.

50	WHAT WE CLAIM IS:- 1. A catalytic process for feedstock with a catalyst	dewaxing gas o	il feedstock, comprisin	ng contacting said gas oil	50

silica/alumina mole ratio of at least 12 and a constraint index within the approximate range of 1 to 12. in the presence of from about 0.1 to about 15 moles of water/mole of gas oil 55 feedstock.

- The process of Claim 1 wherein said crystalline aluminosilicate zeolite is ZSM-5.

 The process of Claim 1 wherein said crystalline aluminosilicate zeolite is ZSM-11.

 The process of Claim 1 wherein said crystalline aluminosilicate zeolite is ZSM-12.
- 60
- 4. The process of Claim 1 wherein said crystalline aluminosilicate zeolite is ZSM-12.
 5. The process of Claim 1 wherein said crystalline aluminosilicate zeolite ZSM-35.
 6. The process of Claim 1 wherein said crystalline aluminosilicate zeolite is ZSM-38.
 7. The process of any one of Claims 1 to 6 wherein said process is conducted at a temperature from about 450°F to about 800°F, a pressure of from about 50 psig to about 3000 psig, a liquid hourly space velocity of from about 0.1 hr⁻¹ to about 20 hr⁻¹, a hydrogen circulation rate of from 0 to about 10.000 scf/bbl, and wherein said mole ratio of water/gas

	oil feedstock is from about 0.1 to about 5. 8. The process of any one of the preceding Claims wherein said gas oil feedstock is a	
	hydrocarbon oil boiling above about 350°F.	
	9. Process of catalytically dewaxing gas oil substantially as described herein with	
5.	reference to any one of Examples 3, 5, 6 or 9.	5
	10. Gas oil which has been dewaxed by the process of any one of the preceding Claims.	•
